Igneous and sedimentary rocks mainly undergo this change and become metamorphic rocks. The existing rock type which undergoes a change is referred to as the protolith. Hence, the study of metamorphic rocks provides an understanding of the pressure and temperatures deep within the earth's crust. Gneiss, marble, slate, schist, and quartzite are some of the different types of metamorphic rocks.

A rock is any naturally occurring solid mass or aggregate of minerals or mineraloid matter. It is categorized by the minerals included, its chemical composition and the way in which it is formed. Rocks are usually grouped into three main groups: igneous rocks, metamorphic rocks and sedimentary rocks. Rocks form the Earth's outer solid layer, the crust, and most of its interior, except for the ...

Slate and chalk are both sedimentary rocks. The sedimentary layers slowly sink into the crust. As the rock sink deeper, the pressure and temperature increase, and the rocks undergo metamorphoses. They are then called metamorphic rocks. Limestone, for example, is transformed into a colorful metamorphic rock, marble. The natural movements of Earth's crust can thrust sedimentary and metamorphic layers toward the surface or push them deeper into the mantle.
