Purkinje cells from rat are known to express both low- and high-threshold Ca^{2+} channels throughout development (Kaneda et al. 1990; Nam & Hockberger, 1997). However, electrophysiological and

immunohistochemical evidence suggest a change in the relative contributions of specific Ca²⁺-channel subunits over time that matches the development of spike output properties reported here.

Rat embryos do have the advantage of being much larger than mouse embryos and easy to breed. Another advantage of rats is in vision development studies, as that retinal development continues postnatally (most vertebrate neurological systems are difficult to access during periods of development).

Our developmental studies of the human central nervous system have been going on for close to 20 years. At first, we used the monograph published in 1919 by Hochstetter to view various stages of human brain development, then matched them to rat brain development (see
